Cloud Architecture, Tooling and Security (CATS) Team
Netflix

Identity and access management at real scale is a tooling and data problem before it's a policy problem — which is exactly the lens I've built my career around, securing access across heterogeneous cloud and vendor ecosystems.

At Trend Micro/Cysiv, I implemented IAM policies and access controls directly in both AWS and GCP, and architected a Python-based orchestration framework spanning nine distinct SIEM/EDR platforms — building the API tokens, roles, and permissions layer needed to securely integrate each one via its native API. That meant designing secure access patterns for nine separate third-party integrations, each with its own authentication model, and building reusable adapters and scrappy internal tooling in Python to manage all of them at once.

That framework ran through a full GitLab CI/CD pipeline, with multithreading to handle concurrent operations across many customers and vendor platforms in parallel — the same kind of self-serve, foundational tooling that a paved-path GCP/AWS access program depends on. I also evaluated security controls and tooling across this same wide vendor landscape as part of ongoing threat-assessment work.

I'd welcome the chance to talk through how that hands-on IAM and cross-platform access-management background fits the CATS team's roadmap.
