Amazon — AWS Security

I've spent 12 years building the statistical and machine-learning models that find cyber threats inside massive-scale infrastructure telemetry — exactly the anomaly detection, predictive modeling, and real-time risk-assessment work this AWS Security data scientist role is built around.

At Trend Micro/Cysiv, I built unsupervised clustering models to group network devices by behavioral feature similarity and time-series anomaly detection content covering authentication volume anomalies and process-chain deviations — production ML-based detection logic, not research exercises. I ran exploratory data analysis at scale on GCP Dataproc clusters using PySpark/SparkSQL and Zeppelin notebooks, and built a homegrown Apache Beam/Dataflow pipeline to retrieve high-volume historical data for investigations — the same big-data-processing muscle this role's SageMaker/EMR-scale work calls for, applied on a different hyperscale cloud. That statistical and ML detection work scaled into 2,300+ production detection rules across the MITRE ATT&CK matrix, built on a data-engineering pipeline I helped own spanning 220+ log sources.

More recently at DOE/NNSA, I built a UEBA detection layer directly on top of custom data transforms to statistically surface anomalous entity behavior — the same automated risk-assessment and pattern-recognition work described in this role's key responsibilities. I also bring direct, hands-on GenAI experience applied to security: prompt engineering for false-positive triage and automated detection-content generation, and using GenAI to orchestrate detection-rule deployment across SIEM APIs — real groundwork for expanding LLM agent pipelines in a security context. My M.S. in Physics centered on numerical data analysis and modeling, the quantitative foundation behind all of it.

I'd welcome the opportunity to bring that same statistical rigor and security-focused ML experience to protecting AWS customers at scale.
